ANSWERS TO EVEN-NUMBERED EXERCISES

2. What are two ways you can execute a shell script when you do not have execute permission for the file containing the script? Can you execute a shell script if you do not have read permission for the file containing the script?

You can give the name of the file containing the script as an argument to the shell (for example, **bash** *scriptfile*, where *scriptfile* is the name of the file containing the script).

Under bash you can give either of the following commands:

```
$ . scriptfile
```

\$ source scriptfile

Because the shell must read the commands from the file containing a shell script before it can execute the commands, you must have read permission for the file to execute a shell script.

4. Assume you have made the following assignment:

\$ person=zach

Give the output of each of the following commands:

a. echo \$person

zach

b. echo '\$person'

\$person

c. echo "\$person"

zach

6. Assume the /home/zach/grants/biblios and /home/zach/biblios directories exist. Give Zach's working directory after he executes each sequence of commands given. Explain what happens in each case.

a.
 \$ pwd
 /home/zach/grants
\$ CDPATH=\$(pwd)
\$ cd
\$ cd biblios

After executing the preceding commands, Zach's working directory is /home/zach/grants/biblios. When CDPATH is set and the working directory is not specified in CDPATH, cd searches the working directory only after it searches the directories specified by CDPATH.

b.
 \$ pwd
 /home/zach/grants
 \$ CDPATH=\$(pwd)
 \$ cd \$HOME/biblios

After executing the preceding commands, Zach's working directory is /home/zach/biblios. When you give cd an absolute pathname as an argument, cd does not use CDPATH.

8. Give the following command:

\$ sleep 30 | cat /etc/inittab

Is there any output from sleep? Where does cat get its input from? What has to happen before the shell displays another prompt?

There is no output from sleep (try giving the command sleep 30 by itself). The /etc/inittab file provides input for cat (when cat has an argument, it does not check standard input). The sleep command has to run to completion before the shell displays another prompt.

10. Write a shell script that outputs the name of the shell executing it.

There are many ways to solve this problem. The following solutions are all basically the same. These scripts take advantage of the PPID shell variable, which holds the PID number of the shell that is the parent of the process using the variable. They also use the fact that echo changes multiple sequential SPACEs to a single SPACE. The cut utility interprets multiple sequential SPACEs as multiple delimiters, so the script does not work properly without echo.

```
$ cat a
pid=$PPID
line=$(ps | grep $pid)
echo $line | cut --delimiter=" " --fields=4
```

```
$ cat a2
pid=$PPID
echo $(ps | grep $pid) | cut --delimiter=" " --fields=4
$ cat a3
echo $(ps | grep $PPID) | cut --delimiter=" " --fields=4
```

The easy solution is to give the following command:

\$ echo \$0

The \$0 is the first command-line token, which is usually the name of the script or program that is running (page 1041). In some cases, such as when you call the script with a relative or absolute pathname, this outcome may not be exactly what you want.

12. Add the exit status of the previous command to your prompt so that it behaves similarly to the following:

```
$ [0] ls xxx
ls: xxx: No such file or directory
$ [1]
```

The following command sets up the prompt described in the question:

```
PS1='[$?] '
```

14. Implement the basename utility, which writes the last component of its pathname argument to standard output, as a bash function. For example, given the pathname a/b/c/d, basename writes d to standard output:

```
$ basename a/b/c/d
```

The following function is named **bn** to distinguish it from the basename utility. It behaves the same way as basename.
